A PRACTICAL PLAN FOR THE GARDEN TEAM

Production plan - PRIVATE {note}, east; $&

October 2026 to September 2027

LOCATION	CLIMATE	PLAN PERIOD	GENERATED
No site set	Not set	October 2026 to September 2027	21 Oct 2026

A crop plan should reduce uncertainty. It should show the garden team what to prepare, plant, harvest and buy - without making them decode the system behind it.

0.0 m²
growing space
0 beds

Not shown
known benchmark total
no verified kg/m² crop entry

Not shown
benchmark density
known total ÷ whole growing area, to compare plans

Not calculated
loss-adjusted total
confirm a loss allowance from actual records

0/12
fresh-picking months
timing windows only; no monthly kg inferred

PLAN SIGNALS

- No crop in this plan has a verified kg/m² food-yield benchmark, so no kilogram comparison is shown.
- Oct, Nov, Dec carry the most planned jobs - counted as jobs, not hours.

DECISIONS TO MAKE

- Check actual household demand and recorded harvests; the benchmark comparison is not a meal or surplus guarantee.
- Check who is available before the Oct-Dec job peak, and time the work against real hours.
- Confirm a loss allowance from actual records before calculating a usable total.

How the totals are calculated

No kilogram total is shown because this plan has no crop with a verified kg/m² food-yield benchmark.

An unavailable benchmark is not a 0kg harvest. Record actual harvests on the monthly record sheet.

HOW MUCH TO TRUST THIS PLAN

No agronomist has checked this plan. It is built from your own map, from climate and soil data measured by satellites and global models, and from published South African growing guidelines. It is put together carefully and in good faith - but it is a starting point, not an instruction.

Use your own judgement alongside it. A computer cannot see your land. It does not know where the water stands after heavy rain, which corner the frost settles in, what failed here last year, or what your family will actually eat. You do.

Soil is the figure most likely to be wrong. Ours comes from a global model that reads a wide area, and real soil can change from one end of a single field to the other. If any number here matters to a decision you are spending money on, a soil test is the only way to know. You can upload one and the plan will be rebuilt around your real numbers.

Show this to your local agricultural extension officer. They know your district, your rainfall and your pests in a way no model does, and they can correct in ten minutes what would otherwise cost you a season. It costs nothing, and it is the single most useful thing you can do with this document.

Expect some of it to be wrong. Write down what you actually planted and what you actually harvested. Every season you record makes the next plan fit your land more closely than this one does - that is the point of it.

Published optimum-condition maturity endpoints are planning slots, not promises. Before any successor is sown or transplanted, confirm the previous crop is finished and the bed is actually clear; crops may mature later.

How this plan was put together

From the plan suggested in October 2026. Anything changed by hand since is not described here.

WHAT TO WATCH

Amadumbe (taro) was chosen, but it has no sowing month on the summer-rainfall, hard-frost calendar this farm uses - the sowing guides this plan follows give none for this calendar (frost or the rainfall season, usually), so making room would not help. Ask your extension officer before trying it here.

Swiss chard (spinach) was chosen but didn't fit anywhere in this plan - every sowing window it has was already committed to other crops, or ruled out by rotation. Add it by hand if you want to make room. This plan had 1 veg bed (9 m² in all) - add beds on the map to fit more of your choices.

No growing area is mapped yet, so there was nowhere to put the vegetables you chose. Draw a veg bed on the map and run the suggestion again.

Every growing area on your map is a staple plot, and the vegetables you chose need a regular veg bed. Draw a veg bed on the map, or plant them on a plot yourself once you have checked the row layout.

No beds free for family crops once space-hungry vines were placed.

GROUND WITH NO NEW SOWING

1 growing area has a stretch with no new sowing: PRIVATE {note}, east; $& (all year). A staple plot grows one crop across the whole block. Once its course for the year is used, no second staple may follow it. No declared winter cover reaches these months. A vegetable crop could cover them, but the planner will not put a vegetable on a traced field on its own - planted at full block width that is a sizeable commitment, so it is left as your decision. Sowing one by hand, or resting the ground, are both sound choices.

HOW THIS PLAN WAS MADE

Exact crop choices need verified duration and field establishment for scheduling. Yield benchmarks are used only where the catalog has them; missing kilograms are never invented.

Broad automatic choices use crops with verified yield, duration and field spacing so their productivity comparison has a common evidence basis.
